Unfolding schematic formal systems (Feferman '96)

Given a **schematic formal system** S , which operations and predicates, and which principles concerning them, ought to be accepted if one has accepted S ?

Example (Non-finitist arithmetic NFA)

Logical operations: \neg , \wedge , \forall .

$$(1) x' \neq 0$$

$$(2) \text{Pd}(x') = x$$

$$(3) P(0) \wedge (\forall x)(P(x) \rightarrow P(x')) \rightarrow (\forall x)P(x).$$

Schematic formal systems

- The informal philosophy behind the use of schemata is their **open-endedness**
- Implicit in the acceptance of a schemata is the acceptance of any meaningful **substitution instance**
- Schematas are applicable to **any language** which one comes to recognize as embodying meaningful notions

Background and previous approaches

General background: **Implicitness program (Kreisel '70)**

Various means of extending a formal system by principles which are implicit in its axioms.

- Reflection principles, transfinite recursive progressions (**Turing '39, Feferman '62**)
- Autonomous progressions and predicativity (**Feferman, Schütte '64**)
- Reflective closure based on self-applicative truth (**Feferman '91**)

- 1 Introduction

- 4 Unfolding finitist arithmetic
- 5 Unfolding finitist arithmetic with bar rule
- 6 Unfolding feasible arithmetic

How is the unfolding of a schematic system S defined ?

- We have a general notion of (partial) operation and predicate
- Predicates are just special kinds of operations, equipped with an \in relation
- Underlying partial combinatory algebra with pairing and definition by cases:
 - (1) $kab = a$,
 - (2) $sab\downarrow \wedge sabc \simeq ac(bc)$,
 - (3) $p_0(a, b) = a \wedge p_1(a, b) = b$,
 - (4) $dabtt = a \wedge dabff = b$.
- Operations are not bound to any specific mathematical domain

The full unfolding $\mathcal{U}(S)$

- The universe of S has associated with it an additional unary relation symbol, U_S , and the axioms of S are to be relativized to U_S .
- Each function symbol f of S determines an element f^* of our partial combinatory algebra.
- Each relation symbol R of S together with U_S determines a predicate R^* of our partial combinatory algebra with $R(x_1, \dots, x_n)$ if and only if $(x_1, \dots, x_n) \in R^*$.
- Operations on predicates, such as e.g. conjunction, are just special kinds of operations. Each logical operation I of S determines a corresponding operation I^* on predicates.
- Families or sequences of predicates given by an operation f form a new predicate $Join(f)$, the disjoint union of the predicates from f .

The substitution rule

Substitution rule (Subst)

$$\frac{A[\bar{P}]}{A[\bar{B}/\bar{P}]} \quad (\text{Subst})$$

$\bar{P} = P_1, \dots, P_m$: sequence of free predicate symbols

$\bar{B} = B_1, \dots, B_m$: sequence of formulas

$A[\bar{B}/\bar{P}]$ denotes the formula $A[\bar{P}]$ with P_i replace by B_i ($1 \leq i \leq m$)

The three unfolding systems

Definition ($\mathcal{U}(S)$, $\mathcal{U}_0(S)$, $\mathcal{U}_1(S)$)

- $\mathcal{U}(S)$: full (predicate) unfolding of S
- $\mathcal{U}_0(S)$: operational unfolding of S (no predicates)
- $\mathcal{U}_1(S)$: $\mathcal{U}(S)$ without (*Join*)

Remark: The original formulation of unfolding made use of a background theory of typed operations with general Least Fixed Point operator. The present formulation is a simplification of this approach.

The proof theory of the three unfolding systems for NFA

Theorem (Feferman, Str.)

We have the following proof-theoretic characterizations.

- ① $\mathcal{U}_0(\text{NFA})$ is proof-theoretically equivalent to PA.
- ② $\mathcal{U}_1(\text{NFA})$ is proof-theoretically equivalent to $\text{RA}_{<\omega}$.
- ③ $\mathcal{U}(\text{NFA})$ is proof-theoretically equivalent to $\text{RA}_{<\Gamma_0}$.

In each case we have conservation with respect to arithmetic statements of the system on the left over the system on the right.

Finitist arithmetic

Question: What principles are implicit in the actual finitist conception of the set of natural numbers ?

Example (Finitist arithmetic FA)

Logical operations: \wedge , \vee , \exists .

$$(1) \quad x' = 0 \rightarrow \perp$$

$$(2) \quad \text{Pd}(x') = x$$

$$(3) \quad \frac{\Gamma \rightarrow P(0) \quad \Gamma, P(x) \rightarrow P(x')}{\Gamma \rightarrow P(x)}.$$

Note that the statements proved are sequents Σ of the form $\Gamma \rightarrow A$, where Γ is a finite sequence (possibly empty) of formulas. The logic is formulated in Gentzen-style.

Generalization of the substitution rule (Subst)

We have to generalize the substitution rule (Subst) to rules of inference:

Substitution rule (Subst')

Given that the rule of inference

$$\frac{\Sigma_1, \Sigma_2, \dots, \Sigma_n}{\Sigma}$$

is *derivable*, we can adjoin each of its substitution instances

$$\frac{\Sigma_1[\bar{B}/\bar{P}], \Sigma_2[\bar{B}/\bar{P}], \dots, \Sigma_n[\bar{B}/\bar{P}]}{\Sigma[\bar{B}/\bar{P}]}$$

as a new rule of inference.

The proof theory of the three unfolding systems for FA

The **full unfolding of FA** includes the basic logical operations as operations on predicates as well as *Join*.

Theorem (Feferman, Str.)

All three unfolding systems for finitist arithmetic, $\mathcal{U}_0(\text{FA})$, $\mathcal{U}_1(\text{FA})$ and $\mathcal{U}(\text{FA})$ are proof-theoretically equivalent to Skolem's Primitive Recursive Arithmetic PRA.

Support of Tait's informal analysis of finitism.

Extended finitism and the bar rule

In the following

- We will study a natural **bar rule BR** leading to extensions $\mathcal{U}_0(\text{FA} + \text{BR})$, $\mathcal{U}_1(\text{FA} + \text{BR})$ and $\mathcal{U}(\text{FA} + \text{BR})$ of our unfolding systems for finitism
- The so-obtained extensions will all have the strength of Peano arithmetic PA
- This shows one way how Kreisel's analysis of extended finitism fits in our framework

Defining $\mathcal{U}_0(\text{FA} + \text{BR})$: Formulating the bar rule

- The rule **NDS**(f, \prec) says that for each possibly infinite descending chain f w.r.t. \prec there is an x such that $fx = 0$, where f denotes a new constant of our applicative language.
- In general, the **bar rule** **BR** says that we may infer the principle of transfinite induction **TI**(\prec, P) from **NDS**(\prec) for each predicate P .
- We must modify **TI**(\prec, P), since its standard formulation for a unary predicate P is of the form:

$$(\forall x)[(\forall u \prec x)P(u) \rightarrow P(x)] \rightarrow (\forall x)P(x).$$

The idea is to treat this as a rule of the form:

$$\text{from } (\forall u)[u \prec x \rightarrow P(u)] \rightarrow P(x) \text{ infer } P(x).$$

- But we still need an additional step to reformulate the hypothesis of this rule in the language of FA, the basic idea being to use a skolemized form of the universal quantifier.

The key observation

Theorem

Assume that $\text{NDS}(f, \prec)$ is derivable in $\mathcal{U}_0(\text{FA} + \text{BR})$. Then $\mathcal{U}_0(\text{FA} + \text{BR})$ justifies nested recursion along \prec .

Tait's seminal 1961 paper

William Tait: Nested recursion, *Mathematische Annalen*, 143 (1961).

- For each ordinal $\alpha < \varepsilon_0$ let \prec_α be a primitive recursive standard wellordering \prec_α of ordertype α
- Let us write **NDS(f, α)** instead of $\text{NDS}(f, \prec_\alpha)$
- Aim at showing that $\mathcal{U}_0(\text{FA} + \text{BR})$ derives $\text{NDS}(f, \alpha)$ for each $\alpha < \varepsilon_0$
- Use one direction of Tait's famous result, i.e. that nested recursion on ω^α entails ordinary recursion on ω^α or, more useful in our setting, **nested recursion on ω^α entails $\text{NDS}(f, \omega^\alpha)$**
- Tait's argument can be directly formalized in $\mathcal{U}_0(\text{FA} + \text{BR})$

The proof theory of the three unfolding systems for FA with bar rule

Theorem (Feferman, Str.)

All three unfolding systems for finitist arithmetic with bar rule, $\mathcal{U}_0(\text{FA} + \text{BR})$, $\mathcal{U}_1(\text{FA} + \text{BR})$ and $\mathcal{U}(\text{FA} + \text{BR})$ are proof-theoretically equivalent to Peano arithmetic PA.

The language of feasible arithmetic

- The basic schematic system FEA of **feasible arithmetic** is based on a language for binary words generated from the empty word by the two binary successors S_0 and S_1 ; in addition, it includes some natural basic operations on the binary words like, for example, word concatenation and multiplication
- The **logical operations** of FEA are conjunction (\wedge), disjunction (\vee), and the bounded existential quantifier (\exists^{\leq})
- FEA is formulated as a system of sequents in this language: apart from the defining axioms for basic operations on words, its heart is a schematically formulated, i.e. **open-ended induction rule** along the binary words, using a free predicate letter P .

The basic schematic system FEA

Example (Feasible arithmetic FEA)

Logical operations: $\wedge, \vee, \exists^{\leq}$.

(1) defining equations for the function symbols of the language of FEA

$$(2) \frac{\Gamma \rightarrow P(\epsilon) \quad \Gamma, P(\alpha) \rightarrow P(S_i(\alpha)) \quad (i = 0, 1)}{\Gamma \rightarrow P(\alpha)}$$

The strength of the unfoldings of FEA

Theorem (Eberhard, Str.)

The provably total functions of $\mathcal{U}_0(\text{FEA})$ and $\mathcal{U}(\text{FEA})$ are exactly the polynomial time computable functions.

Remarks on the upper bound computation

- A suitable upper bound for $\mathcal{U}(\text{FEA})$ is obtained via the **weak truth theory** T_{PT} introduced by Eberhard and Strahm
- The involved proof-theoretic analysis of T_{PT} using a novel realizability interpretation is due to Eberhard
- To be precise, we consider a slight (conservative) extension of T_{PT} which facilitates the treatment of the generalized substitution rule

Formulating the full unfolding with a truth predicate

The axioms of $\mathcal{U}_\top(\text{FEA})$ extend those of $\mathcal{U}_0(\text{FEA})$ by the following axioms about the truth predicate T :

Truth unfolding

$$\mathsf{T}(x \doteq y) \leftrightarrow x = y$$

$$\mathsf{T}(x \dot{\wedge} y) \leftrightarrow \mathsf{T}(x) \wedge \mathsf{T}(y)$$

$$\mathsf{T}(x \dot{\vee} y) \leftrightarrow \mathsf{T}(x) \vee \mathsf{T}(y)$$

$$\mathsf{T}(\dot{\exists}\alpha x) \leftrightarrow (\exists\beta \leq \alpha)\mathsf{T}(x\beta)$$

$$\mathsf{T}(\pi_i(\bar{x})) \leftrightarrow P_i(\bar{x})$$

The strength of the truth unfolding of FEA

Theorem (Eberhard, Str.)

The provably total functions of $\mathcal{U}_T(\text{FEA})$ are exactly the polynomial time computable functions.

The end

Thank you very much for your attention.
